# BOWEN FLUORESCENCE FROM COMPANION STARS IN X-RAY BINARIES

J. Casares, D. Steeghs, R.I. Hynes, P.A. Charles, R. Cornelisse, and K. O'Brien

## RESUMEN

El resumen será traducido al español por los editores. This paper will review a new technique of detecting companion stars in LMXBs and X-ray transients in outburst using the Bowen fluorescence lines at  $\lambda\lambda 4634$ -4640. These lines are very efficiently reprocessed in the atmospheres of the companion stars, and thereby provide estimates of the  $K_2$  velocities and mass functions. The method has been applied to Sco X-1, X1822-371 and GX339-4 which, in the latter case, provides the first dynamical evidence for the presence of an accreting black hole. Preliminary results from a VLT campaign on V801 Ara, V926 Sco and XTE J1814-338 are also presented.

#### ABSTRACT

This paper will review a new technique of detecting companion stars in LMXBs and X-ray transients in outburst using the Bowen fluorescence lines at  $\lambda\lambda4634$ -4640. These lines are very efficiently reprocessed in the atmospheres of the companion stars, and thereby provide estimates of the  $K_2$  velocities and mass functions. The method has been applied to Sco X-1, X1822-371 and GX339-4 which, in the latter case, provides the first dynamical evidence for the presence of an accreting black hole. Preliminary results from a VLT campaign on V801 Ara, V926 Sco and XTE J1814-338 are also presented.

Key Words: ACCRETION — ACCRETION DISCS — X-RAYS: BINARIES — X-RAY: STARS

#### 1. INTRODUCTION

The Galaxy is populated with  $\sim 50$  known persistent, bright Low Mass X-ray Binaries (LMXBs) whose optical emission is triggered by X-ray reprocessing in the gas surrounding the compact object, mainly the accretion disc. The companion star is  $\sim 10^6$  times fainter than the optical disc and hence completely undetectable. This has hampered dynamical studies of LMXBs which have been restricted so far to radial velocity studies of X-ray transients in quiescence (e.g. Charles & Coe 2003). In several cases, the quiescent companion spectrum is just too faint for current instrumentation (e.g. GX339-4, N Oph 93) or the target is contaminated by a bright line-of-sight star (e.g. Aql X-1, 4U 2129+47). Dynamical studies and mass determination of compact stars in LMXBs can yield new black hole discoveries and, more importantly, probe for the existence of "massive" neutron stars. The latter would rule out soft equations of state and give further support that LMXBs are indeed the progenitors of millisecond pulsars, spun up by accretion.

#### 2. DETECTION OF DONOR IN SCO X-1

A new avenue for mass determination in LMXBs has been opened thanks to the discovery of narrow

high-excitation emission components arising from the irradiated companion in Sco X-1 (Steeghs & Casares 2002), the most prominent being C III 4647-50 and N III 4634-40 (see Fig. 1).

The N III lines are produced by Bowen fluorescence through cascade recombination (which requires He II Ly $\alpha$  seed photons), and must arise on

the irradiated companion because they are extremely narrow ( $FWHM \leq 50~{\rm km~s^{-1}}$ ), and move in antiphase with the compact star (as traced by the He II  $\lambda 4686$  wings). Furthermore, the radial velocity curve is sinusoidal indicating a fixed structure in the binary frame. This work represents the first detection of the companion star in Sco X-1 and opens a new window to extract dynamical information in a population of  $\simeq 20~{\rm LMXBs}$  with optical counterparts.

# 3. GX339-4 AND X1822-371

The Bowen fluorescence diagnostic is a powerful technique also for transient sources as we have clearly demonstrated in Hynes et al. (2003). GX339-4 has been a black hole candidate for decades based on its X-ray properties but no dynamical proof could be found. In summer 2002 we used the opportunity of a new outburst episode to obtain AAT, NTT and VLT spectroscopy which revealed (1) He II velocities modulated with an orbital period of 1.76 d, and (2) narrow N III Bowen components from the companion star with a velocity semi-amplitude of 317  $\pm$  10 km s $^{-1}$ . The implied mass function is 5.8  $\pm$  0.5  $\rm M_{\odot}$  and is robust evidence for an accreting black hole.

The next obvious target is X1822-371 because, at B=16 it is one of the brightest LMXBs. It is also a key system because it is eclipsing, hence the inclination is well constrained, and an X-ray pulsar, making the orbit of the neutron star well constrained. In summer 2002 we obtained AAT spectroscopy but the moderate S/N prevented identification of the narrow fluorescence components in individual spectra. However, we exploited the Doppler Tomography technique which simultaneously uses all the information contained in the phase-resolved emission profiles to reconstruct the emissivity distribution in velocity space (see Casares et al. 2003). Fig. 2 presents the Doppler maps of He II  $\lambda 4686$  and N III  $\lambda 4640$ . The

former displays a classic accretion disc distribution whereas the latter shows a very compact spot consistent with the velocity and phasing of the companion star. The spot velocity, 300 km s<sup>-1</sup>, is a lower limit to the true velocity of the donor star because it is formed on the inner irradiated face. This, combined with the knowledge of the inclination and neutron star's orbit, leads to solid lower limits to the masses of the neutron star and companion of  $1.14 \pm 0.06$  M $_{\odot}$  and  $0.36 \pm 0.02$  M $_{\odot}$ , respectively. Tighter constraints require modelling the *K-correction* (Wade & Horne 1988) to determine the displacement of the irradiated region from the center of mass of the donor star.

## 4. VLT SURVEY

We have started a VLT survey of LMXBs to target new candidates with strong Bowen emission for future studies. These are MM Ser, X1957+115, LU TrA, V926 Sco, GX9+9, GR Mus, V801 Ara and X0614+091. In summer 2003 we observed V926 Sco, V801 Ara and a newly discovered transient, the accreting millisecond pulsar XTE J1814-338 using VLT+FORS2. Our Doppler tomograms enables us to detect the companion star in N III  $\lambda$ 4640 and derive lower limits to their K-velocities of 223, 282 and 345 km s<sup>-1</sup> respectively (Casares et al. 2004a,b in preparation).
